
High number of BK channels with low unitary conductance

- Binding of calcium ions to channels removes a significant amount of calcium from the submembrane region.
- Lower submembrane calcium means some channels don't bind calcium and remain inactivated.

➢ A weaker potassium current.

Low number of BK channels with high unitary conductance

- Fewer calcium ions required to activate channels.
- Higher submembrane calcium is observed with a greater proportion of active channels. Activation is quicker.

➢ A stronger potassium current.
